

COVID-19 testing from a public health perspective:
selection of test, cut-off and sampling scheme
should depend on the purpose of testing

- Joana Pinto da Costa
- Henrique Barros
- Mohamud Sheek-Hussein
- Vladimir Prikazsky
- Polychronis Kostoulas

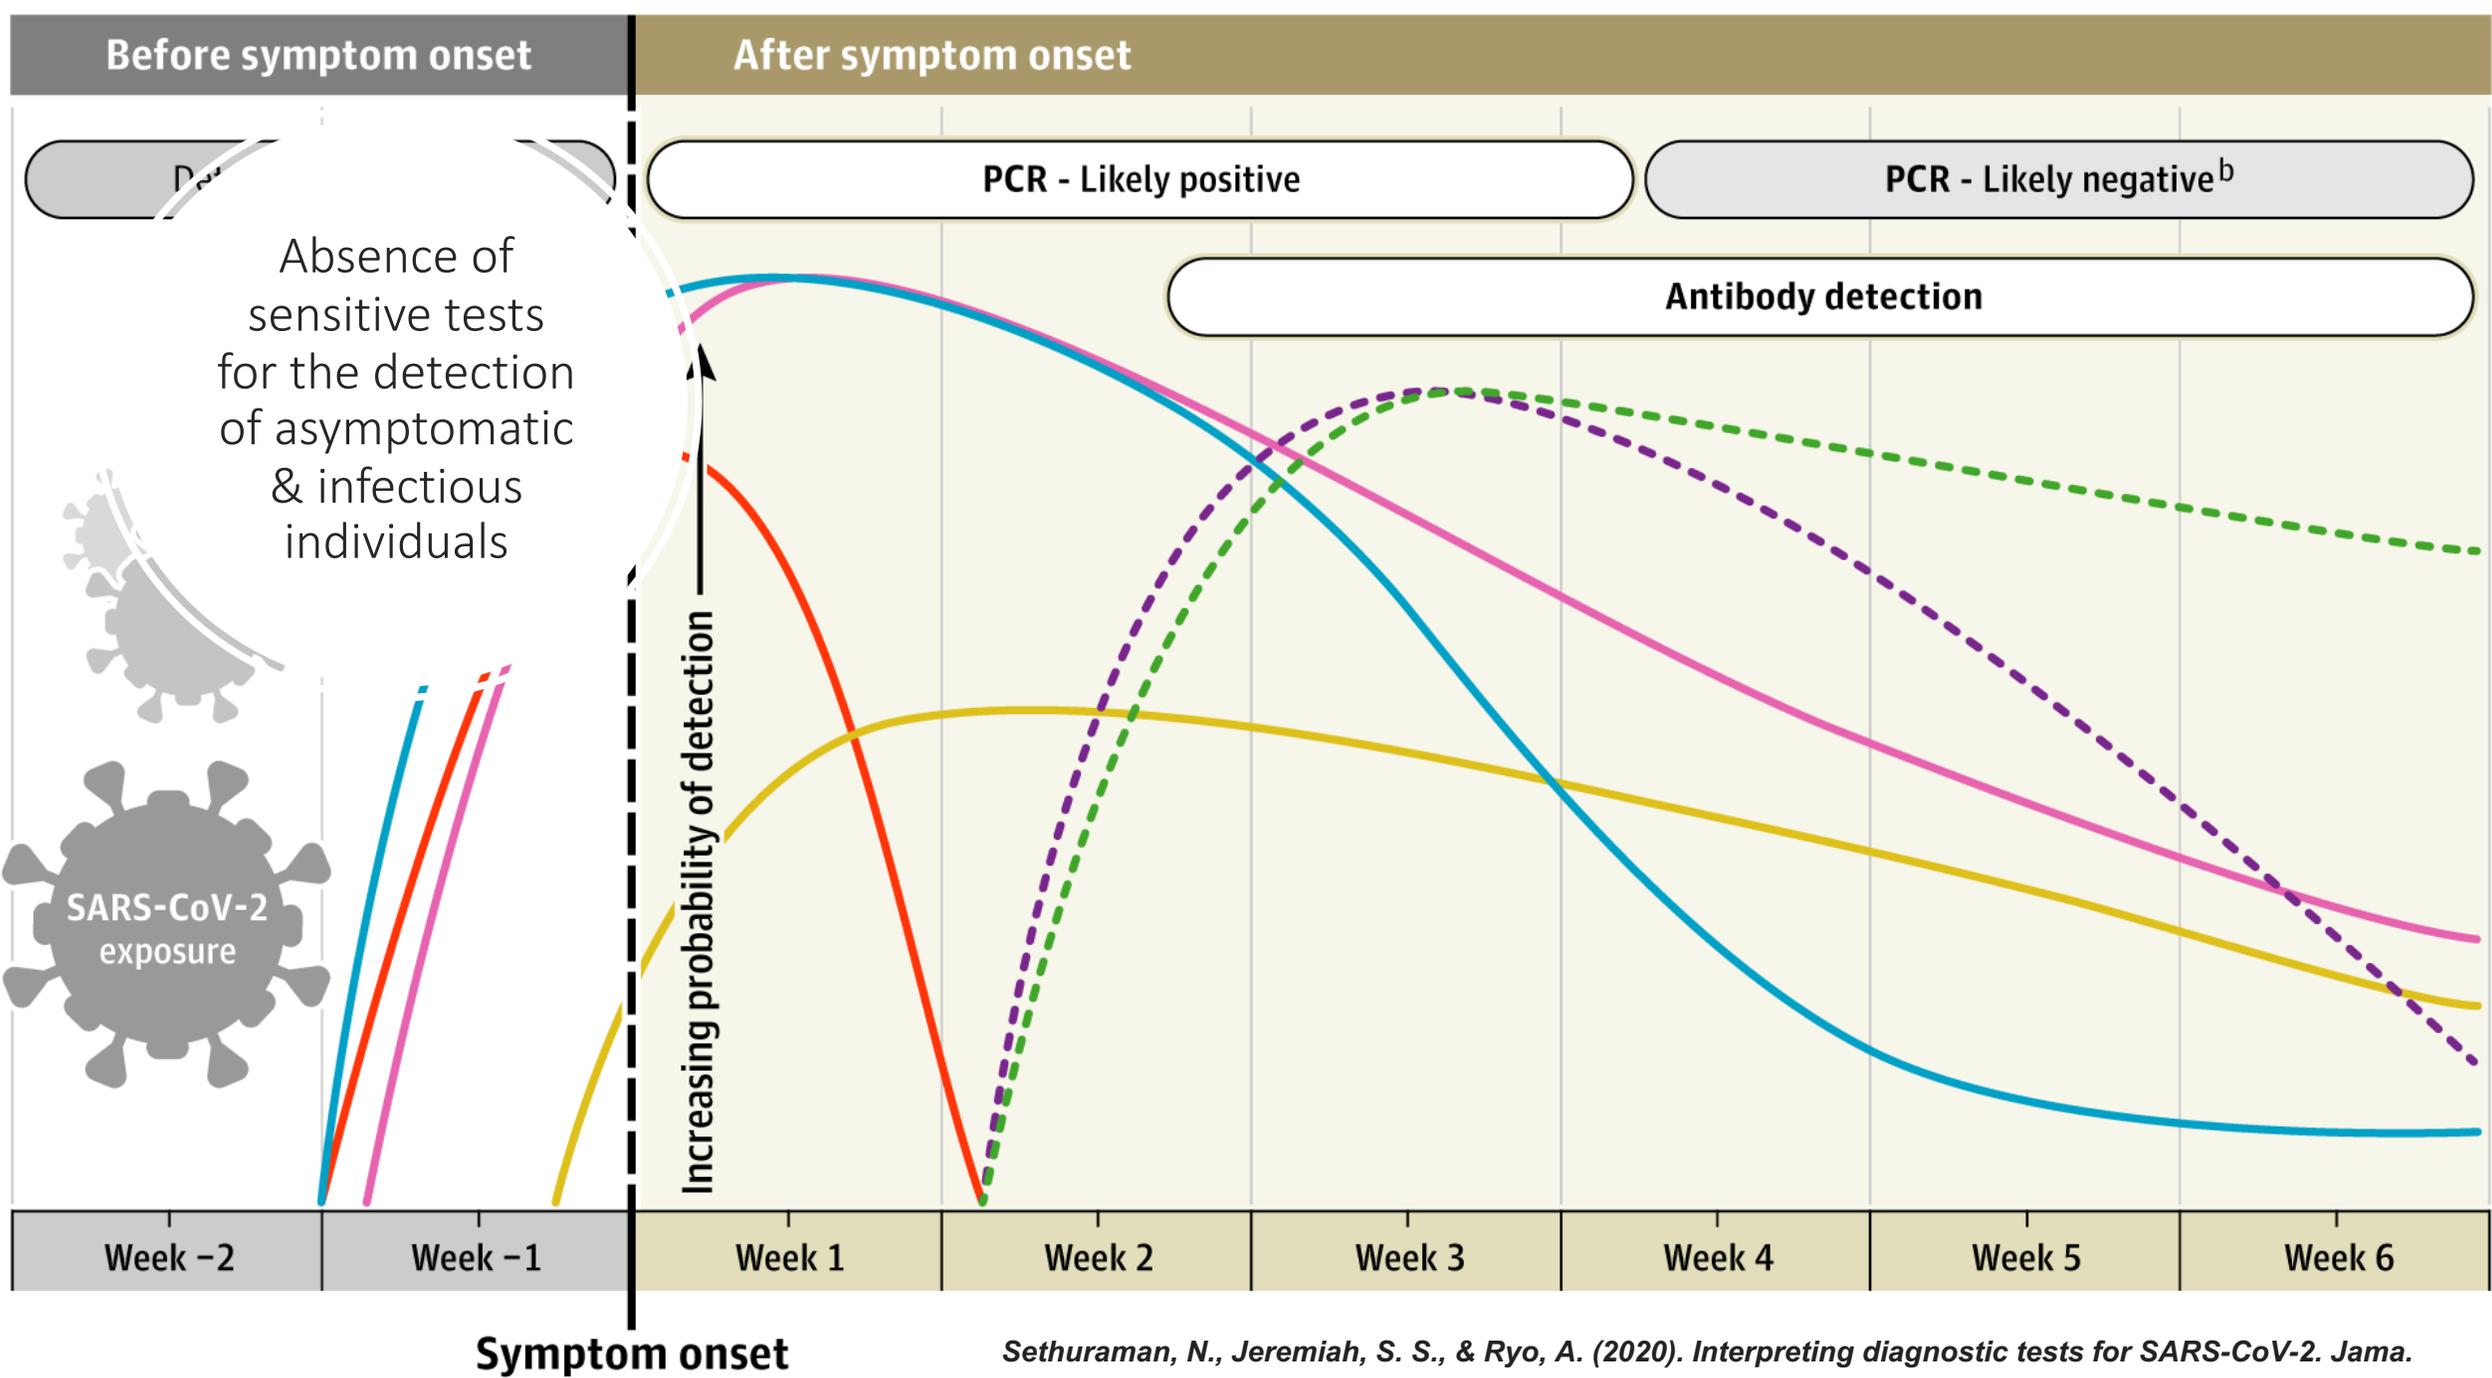

Layout

- Available tests for COVID-19
- Interpretation of test results
- Test Strategies for COVID-19
- Cut-off selection depending on the purpose of testing
- Sampling to estimate COVID-19 prevalence
- Need for population-specific diagnostic accuracy estimates
- Estimation of COVID-19 true prevalence
- Testing infrastructures for COVID-19 surveillance

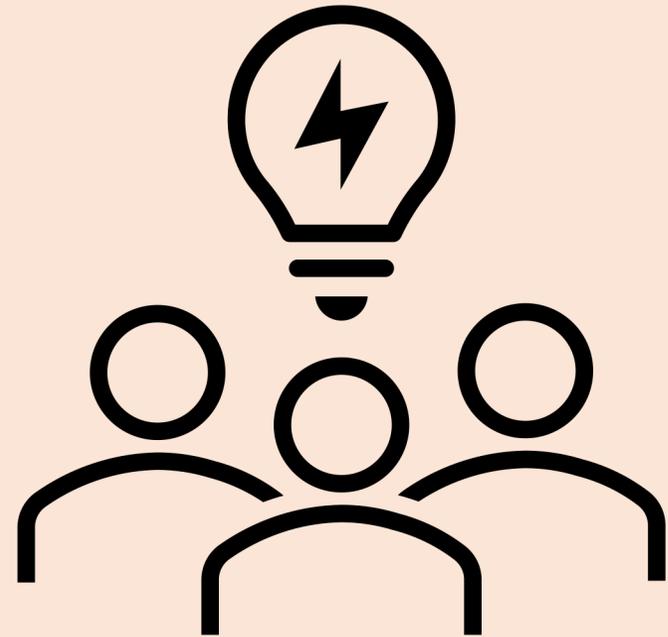

Available tests for COVID-19

- tests aiming to detect the virus or particles of it
- viral RNA – mostly RT-PCR tests
- antigen tests
- tests detecting the immune response of the host
- antibody tests

Sethuraman, N., Jeremiah, S. S., & Ryo, A. (2020). Interpreting diagnostic tests for SARS-CoV-2. *Jama*.

Test & Cut-off
selection
depending on
context & purpose

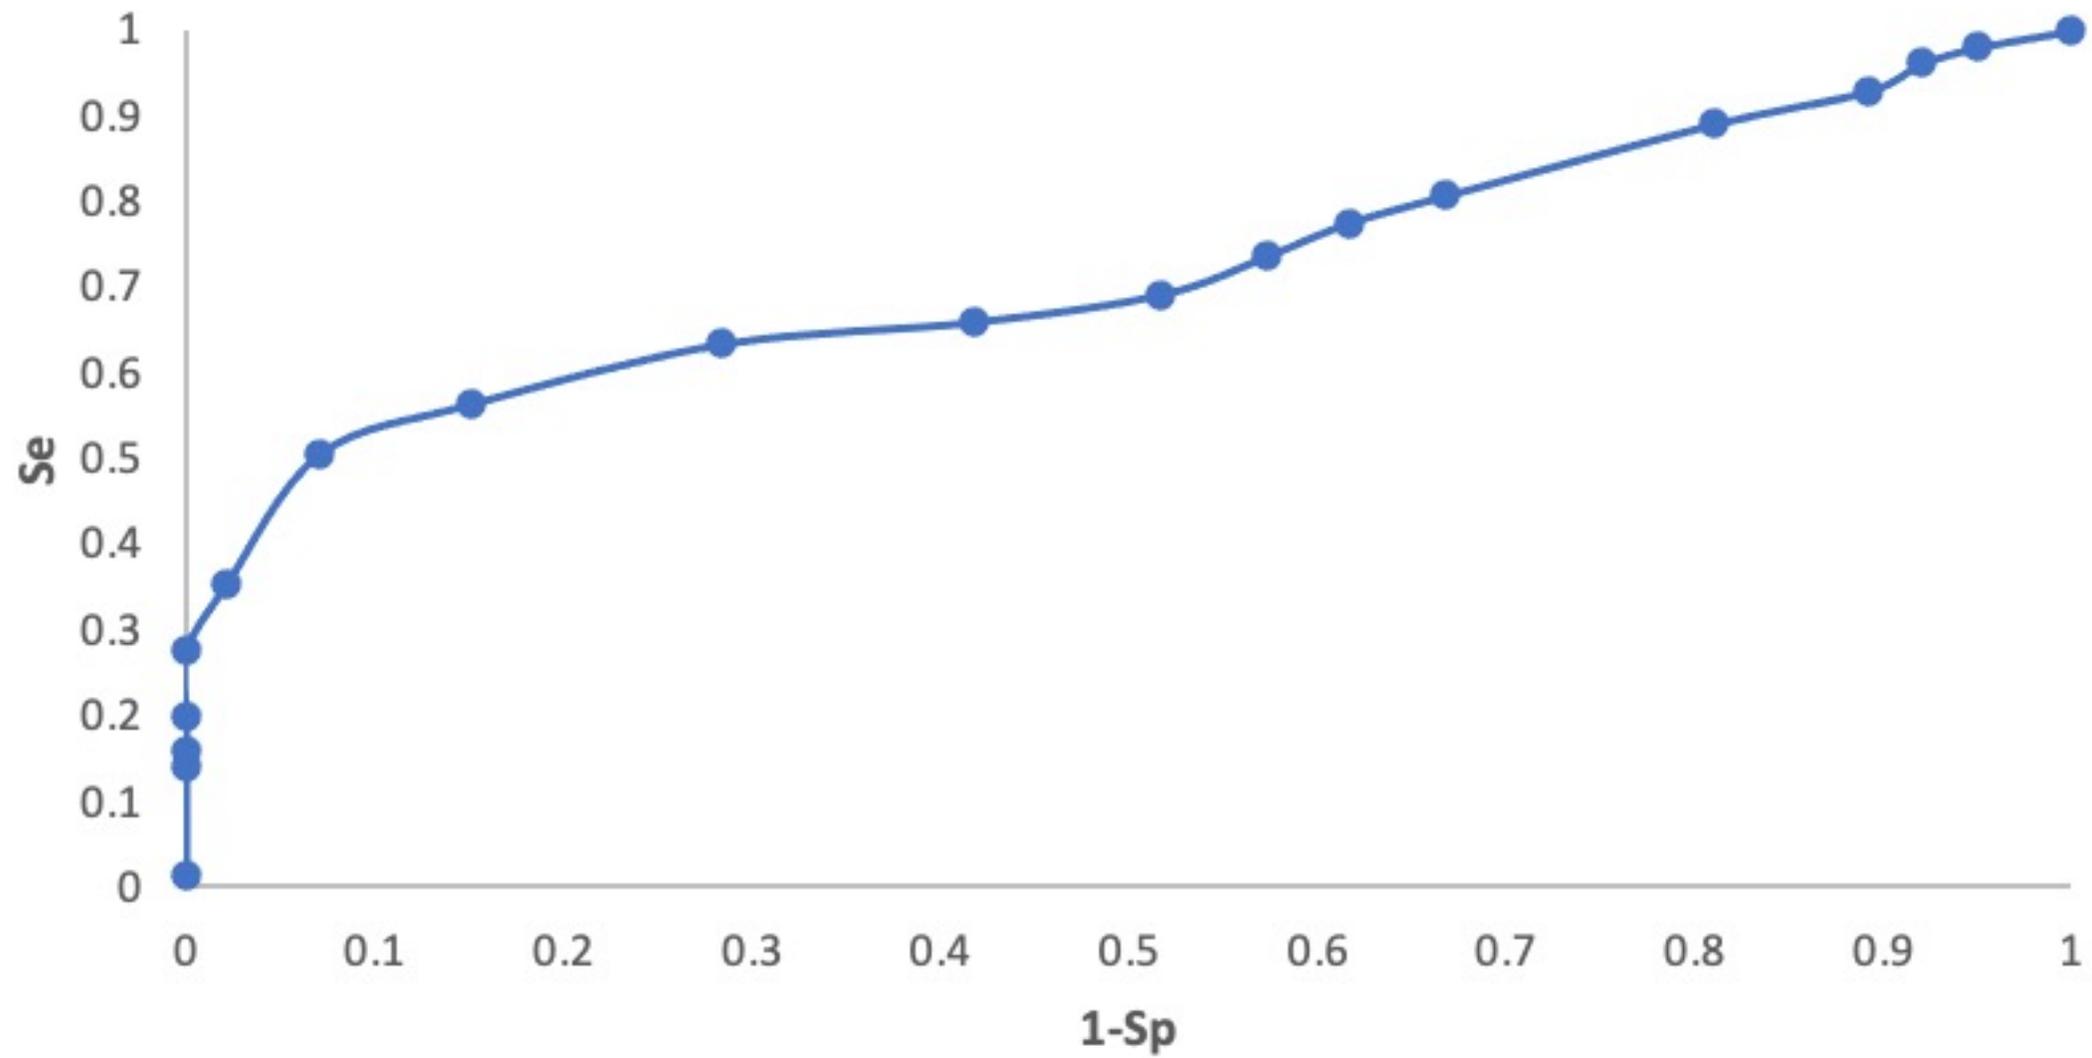

Test Strategies for COVID-19

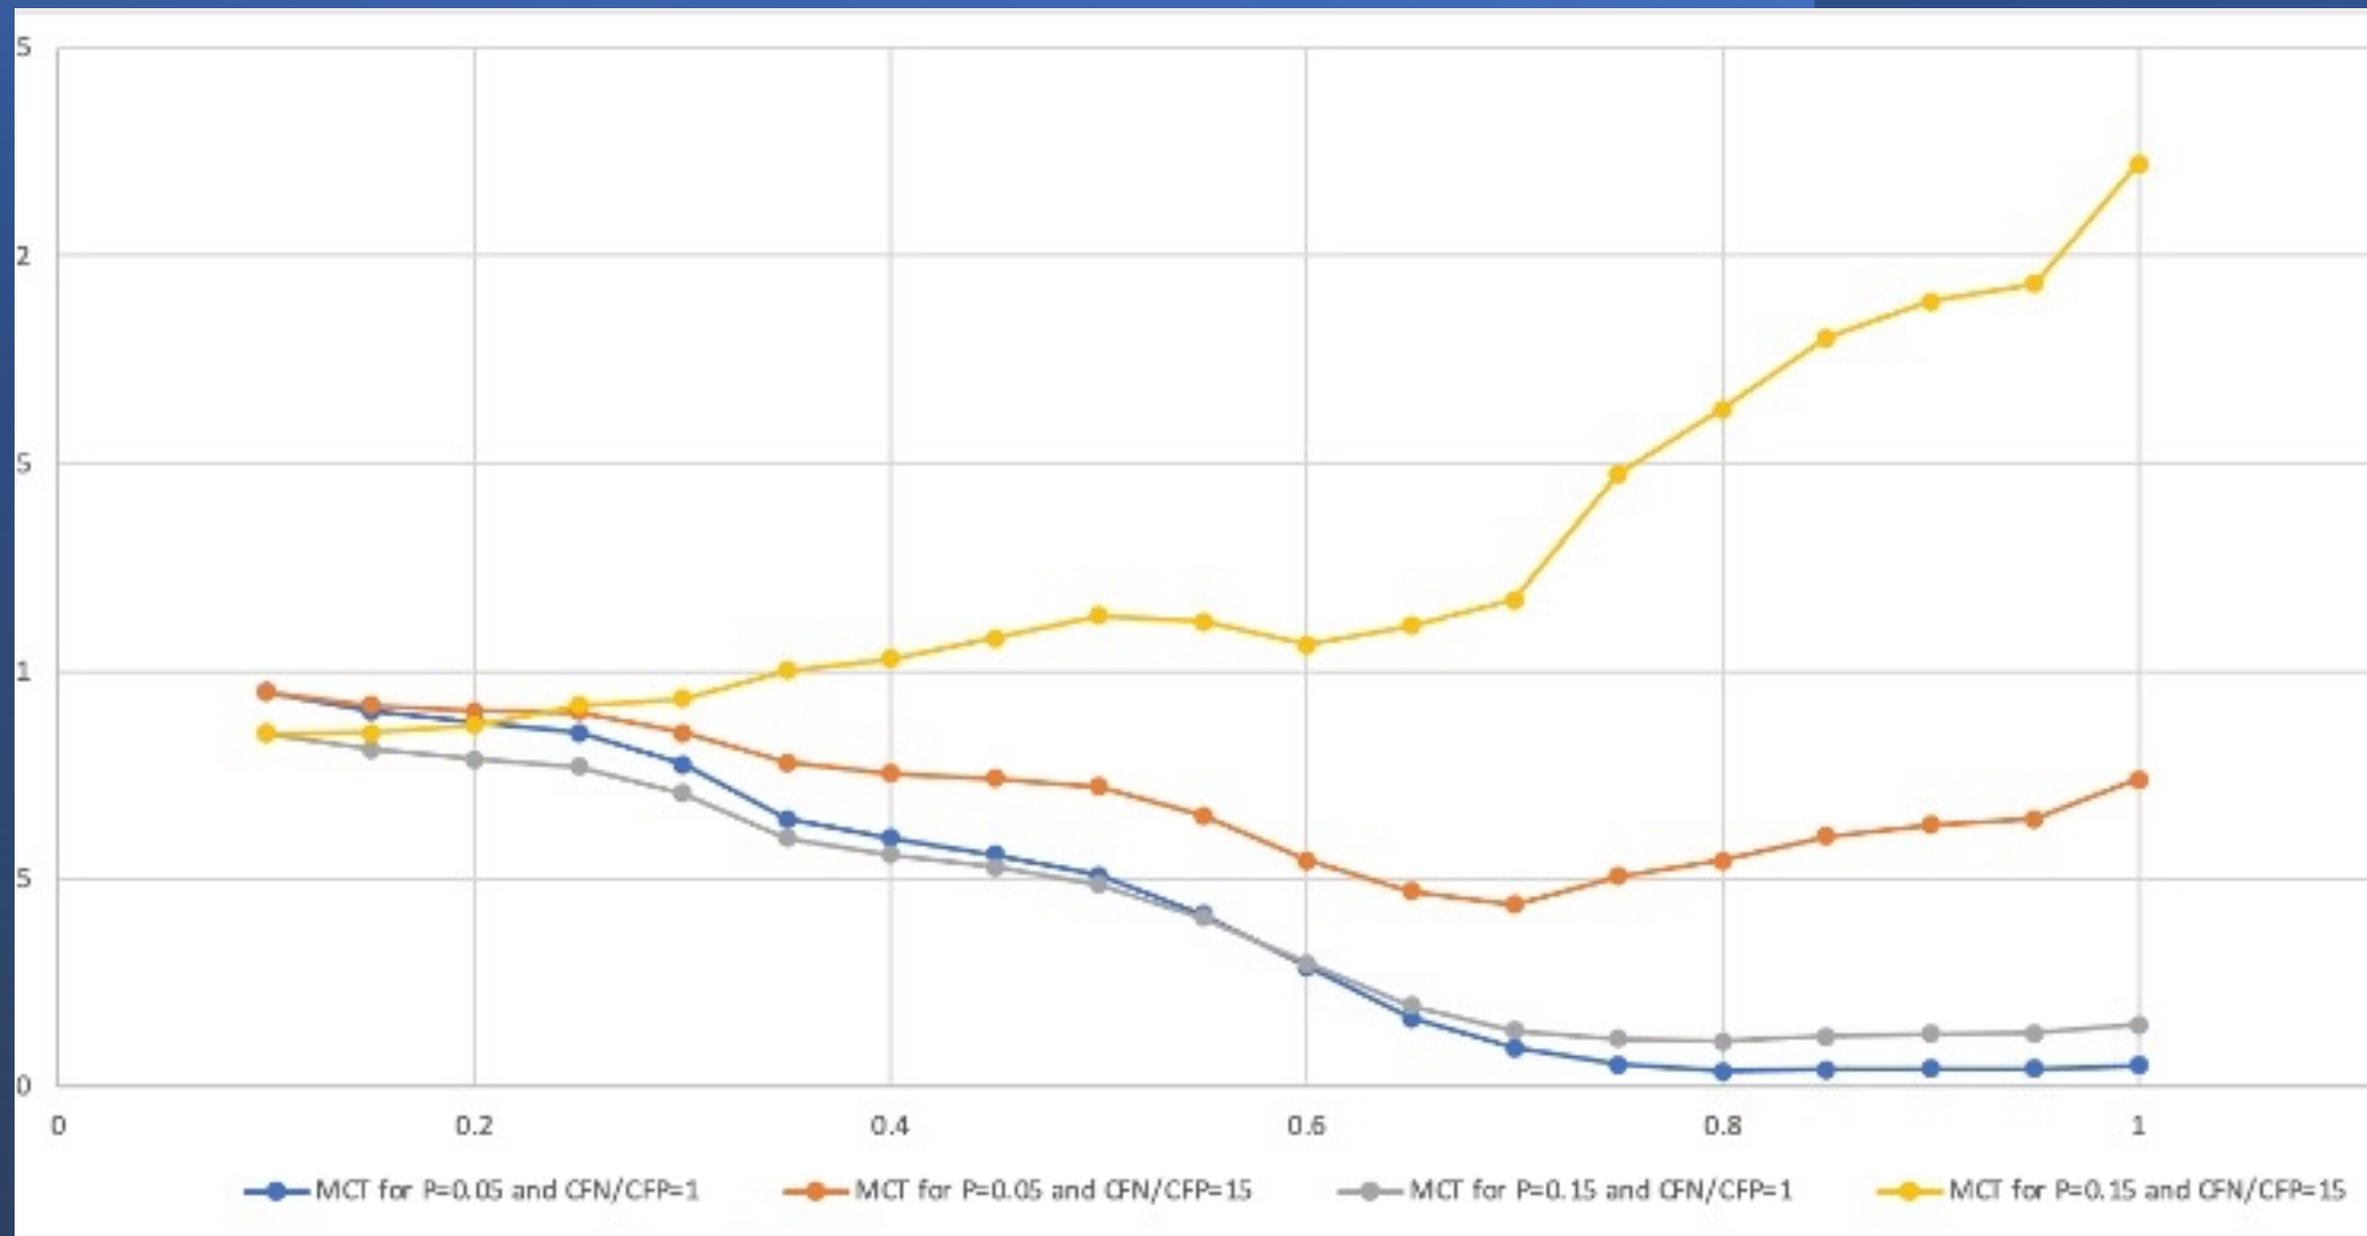

- Should depend on the purpose of testing
- Testing to control the spread
 - early identification of infectious individuals
 - active surveillance scheme
 - repeated testing scheme to increase S_e
- Testing to estimate the prevalence
 - random sampling scheme
 - Representativeness
 - Overall reduction of misclassification rates

Cut-off
selection
depending
on the
purpose of
testing

- **Not** have a fixed cut-off
- Cost-benefit analysis to define the optimal cut-off
 - MTC – relative cost of false negatives (CFN) and false positives (CFP) and the prevalence in the target population

Sampling to estimate COVID-19 prevalence

- Passive surveillance
 - Nonresponse, selection bias and non-probability sampling
- Need for population surveys that will be based on a representative sample

Estimation of COVID-19 true prevalence

- Adjust for the Se and Sp of the diagnostic process
- Se and Sp are population-specific
 - depend on the distribution of the infection stages
- Se and Sp estimates from a clinical setting are not relevant to the Se and Sp estimates of the same tests in the general (and mainly asymptomatic) population

Thank you
